# Project Overview

The objective of the project is to make an Incremental Face Recognition System.

The scenario I work on is :

- the system will authorized student to enter the exam classroom or not ,
- if not and for example the professor want to add them, he can by capturing their picture and entering the name of student

# Dataset Description

## LFW Dataset (Labeled Faces in the Wild)

- 13,000+ images, 5,749 individuals
- Unconstrained real-world conditions (varied lighting, angles)
- Used widely for face recognition & verification

## Complementary Student Dataset

I collected images of some friend and colleges of mine

- Collected images in a clear setting
- Captured using the same webcam setup
- Supports **incremental learning** by adding new users dynamically

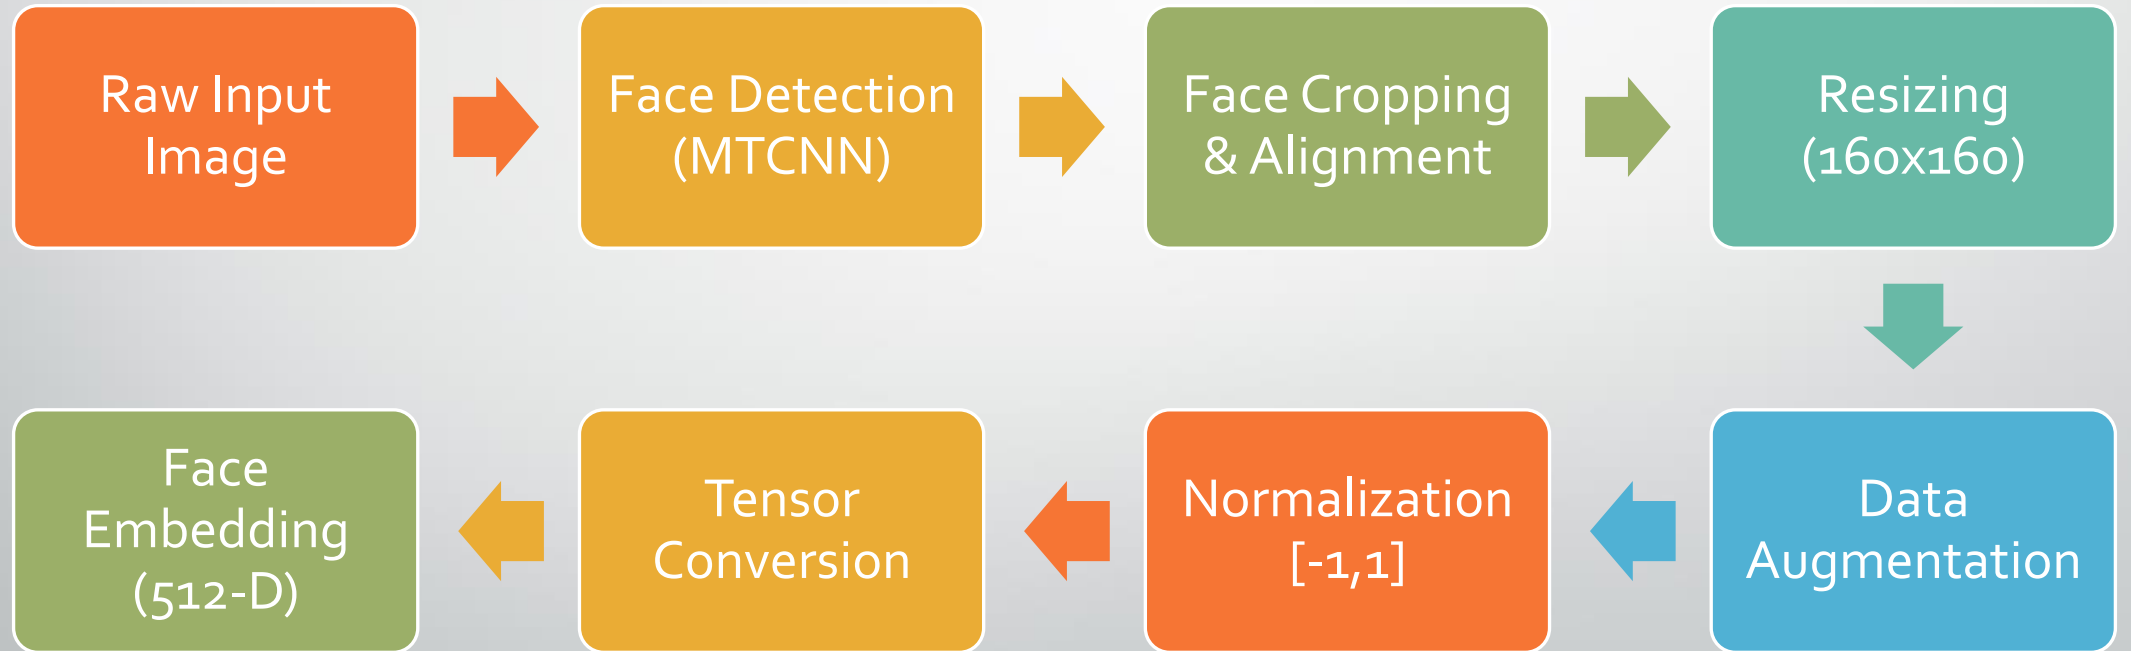

Sample Images from LFW Dataset

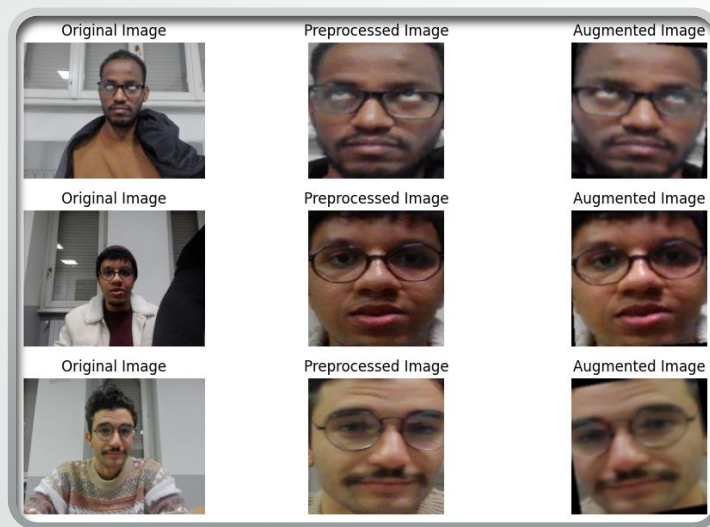

Sample Images from Complimentary Dataset

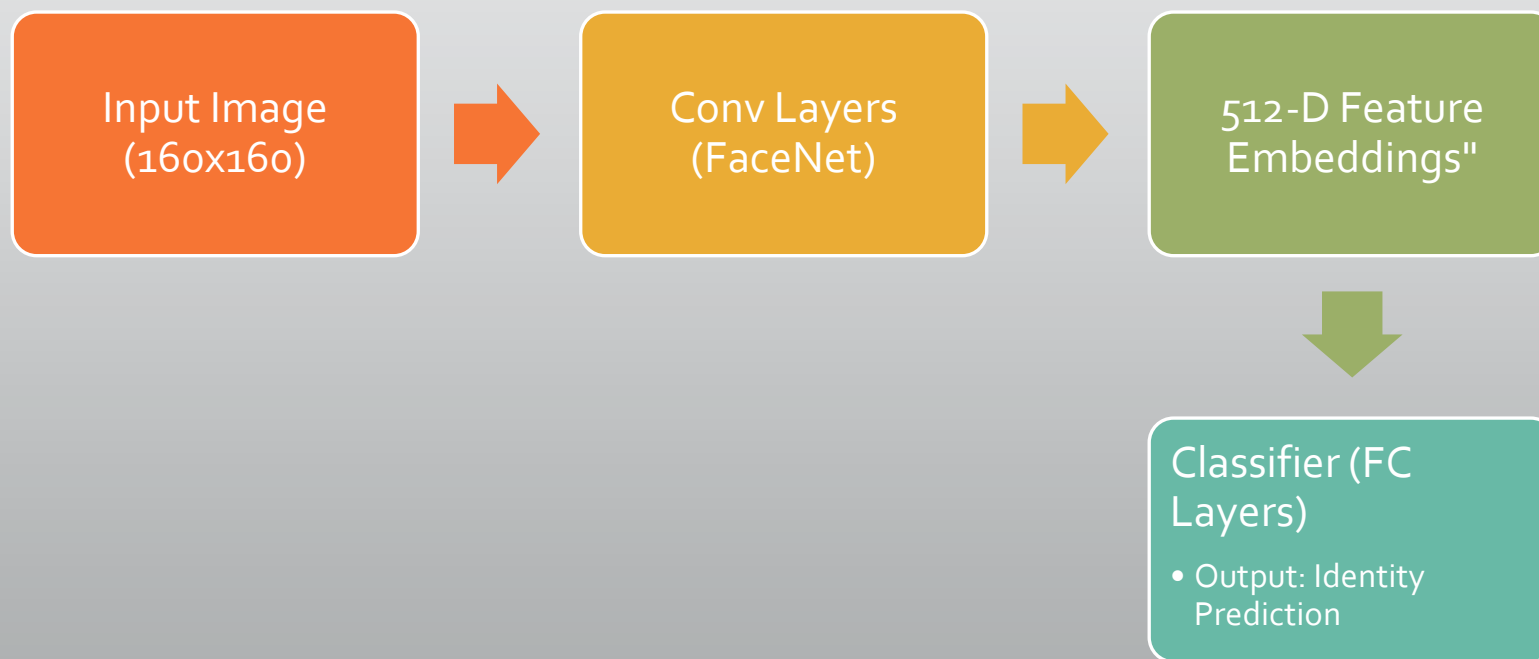

# Data Preprocessing Pipeline

## Images before and after preprocessing

## Model Architecture

# Models Comparison

Feature	Incremental Learning (Used in Project)	Traditional Retraining & Fine-Tuning
Training Efficiency	Efficient, updates without full retraining	Requires full model retraining
New Data Handling	Adds new students dynamically	Needs dataset augmentation for new data
Model Update Speed	Fast, updates embeddings only	Slow, requires backpropagation on full dataset
Computational Cost	Low, no need for entire model retraining	High, needs GPU resources
Memory Usage	Low, stores only embeddings	High, entire model is stored
Risk of Forgetting Old Data	No forgetting, keeps previous data	Risk of catastrophic forgetting
Scalability	Highly scalable for large datasets	Limited, becomes slow as data grows
Real-Time Capability	Yes, works in real-time	Not real-time, requires retraining phase

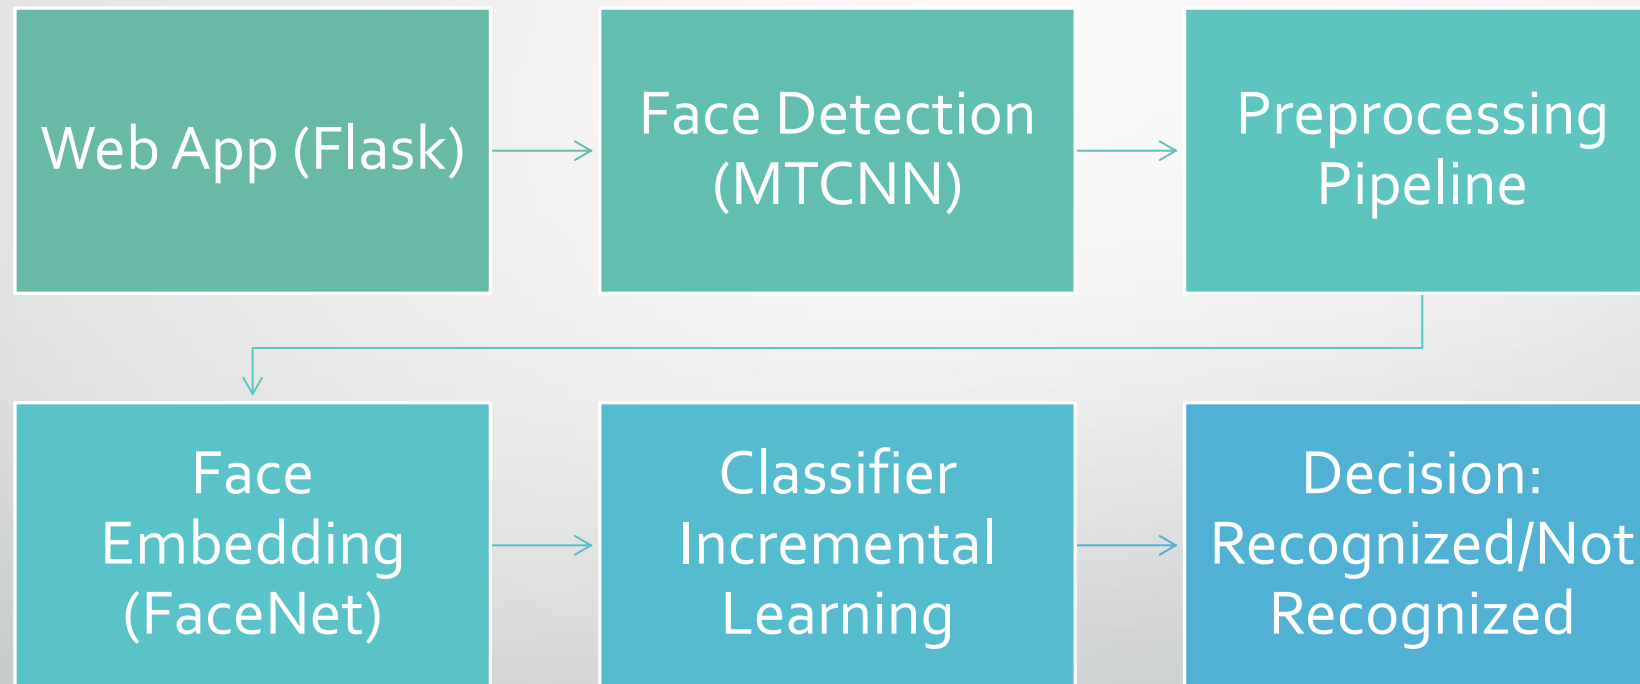

The **Incremental Learning approach** I used in this project falls under "Feature-Based Incremental Learning" (also called Embedding-Based Incremental Learning).

This method does not retrain the full model but instead stores new embeddings for newly added students and updates the classifier dynamically.

## System Architecture - Incremental Face Recognition

## How the Incremental learning work

### Incremental Learning Process in Face Recognition

**Face Detection (MTCNN):** Detects and aligns faces from input images.

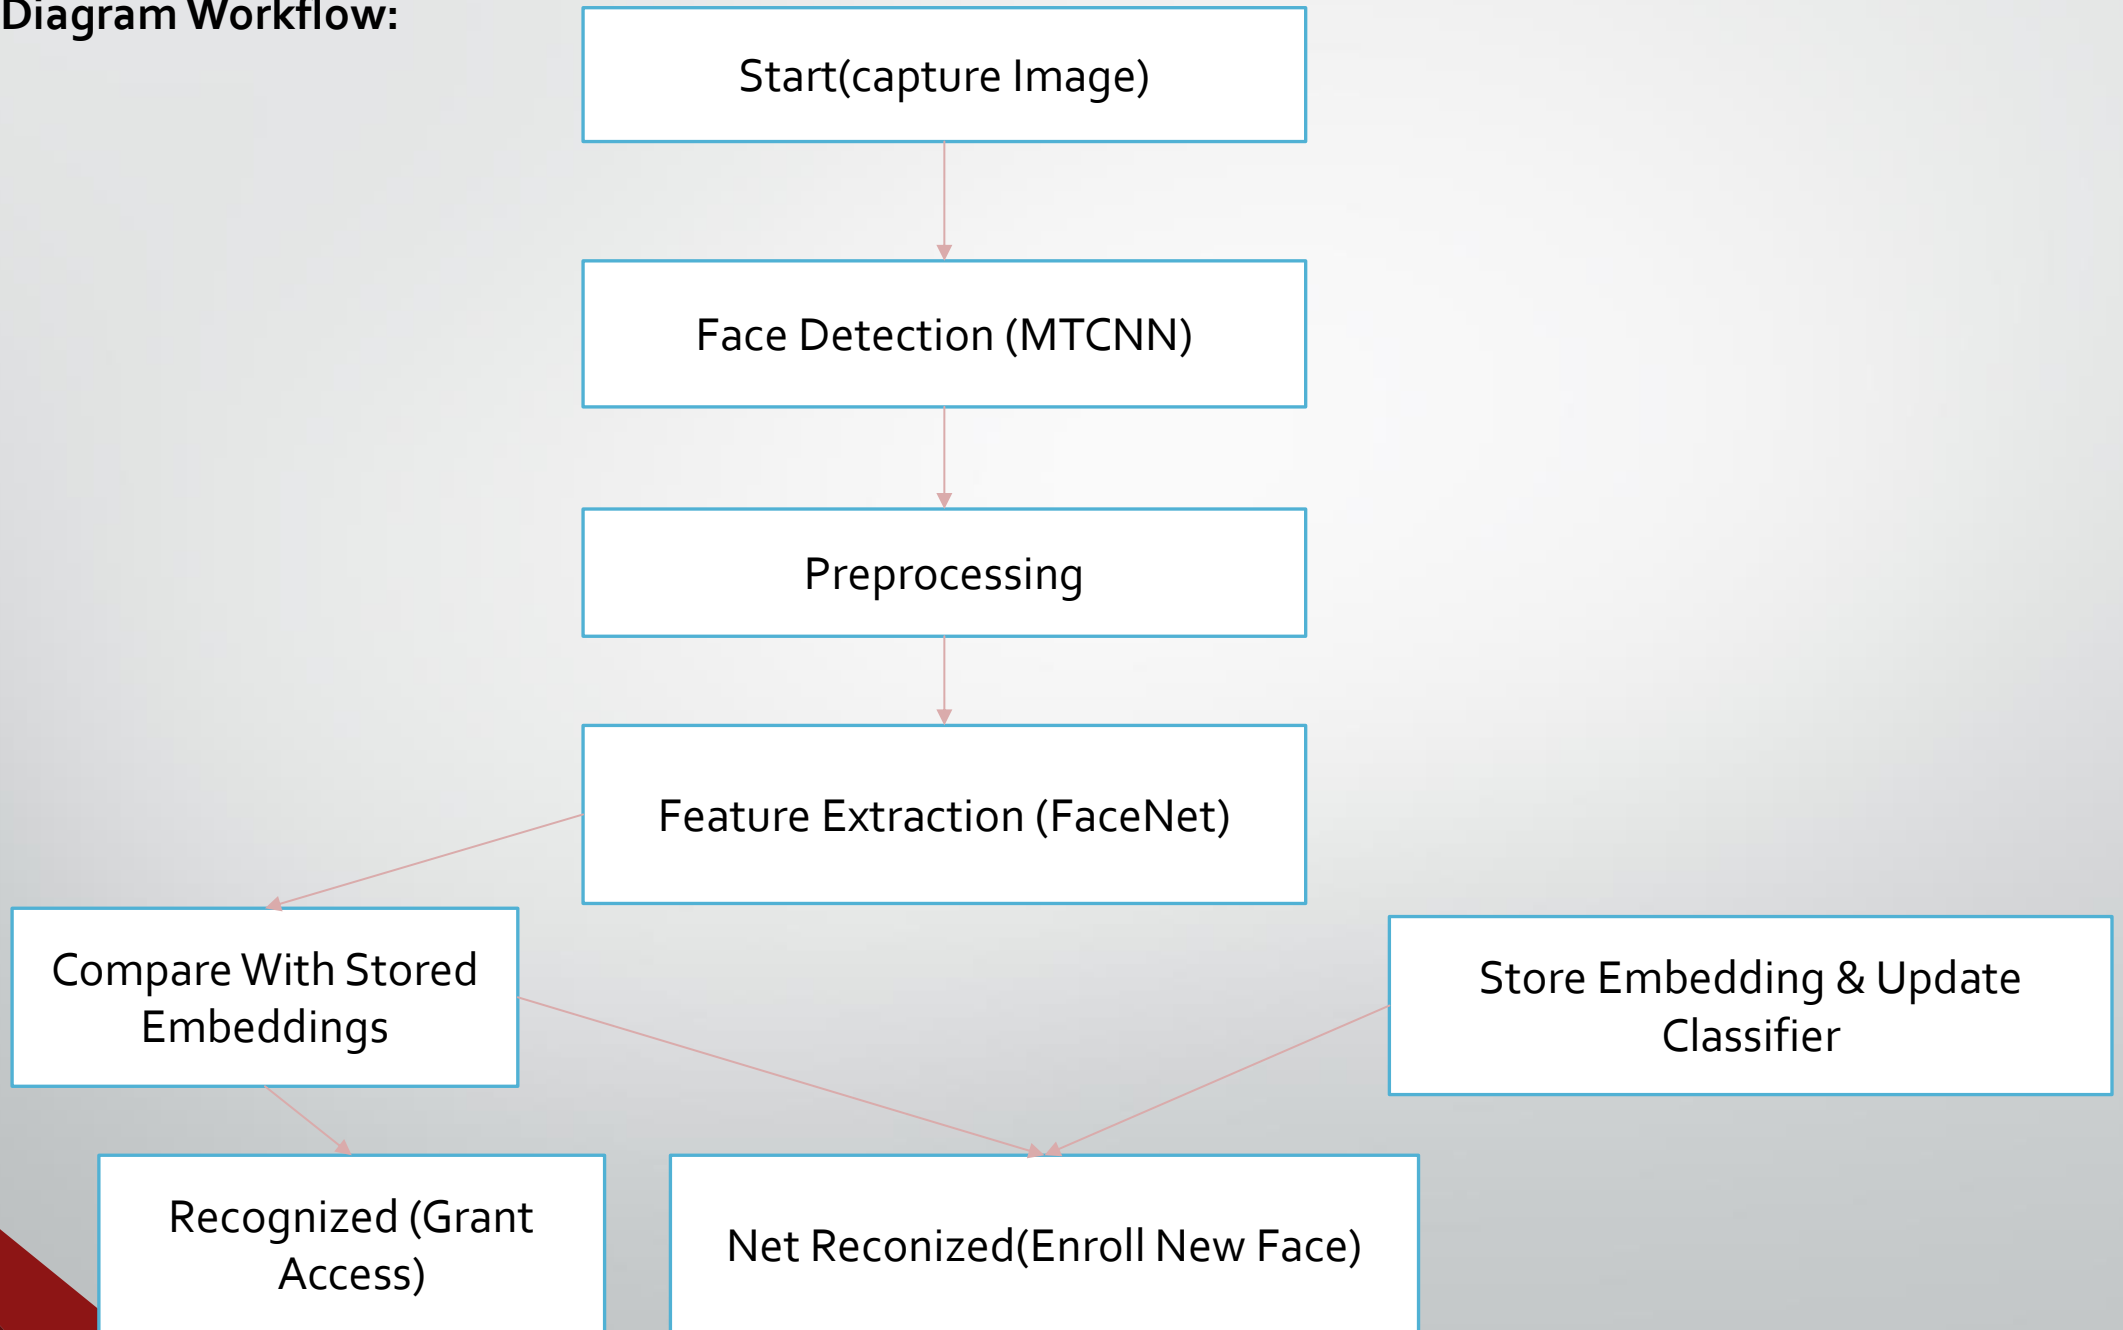

**Feature Extraction (FaceNet):** Converts detected faces into 512-dimensional embeddings.

**Database Update:** New embeddings are **added to the existing database** without retraining the entire model.

**Recognition (Euclidean Distance):** Compares embeddings with stored ones to classify faces.

**Classifier Expansion:** The classification layer updates dynamically to **accommodate new students**.

## Diagram Workflow:

# Results

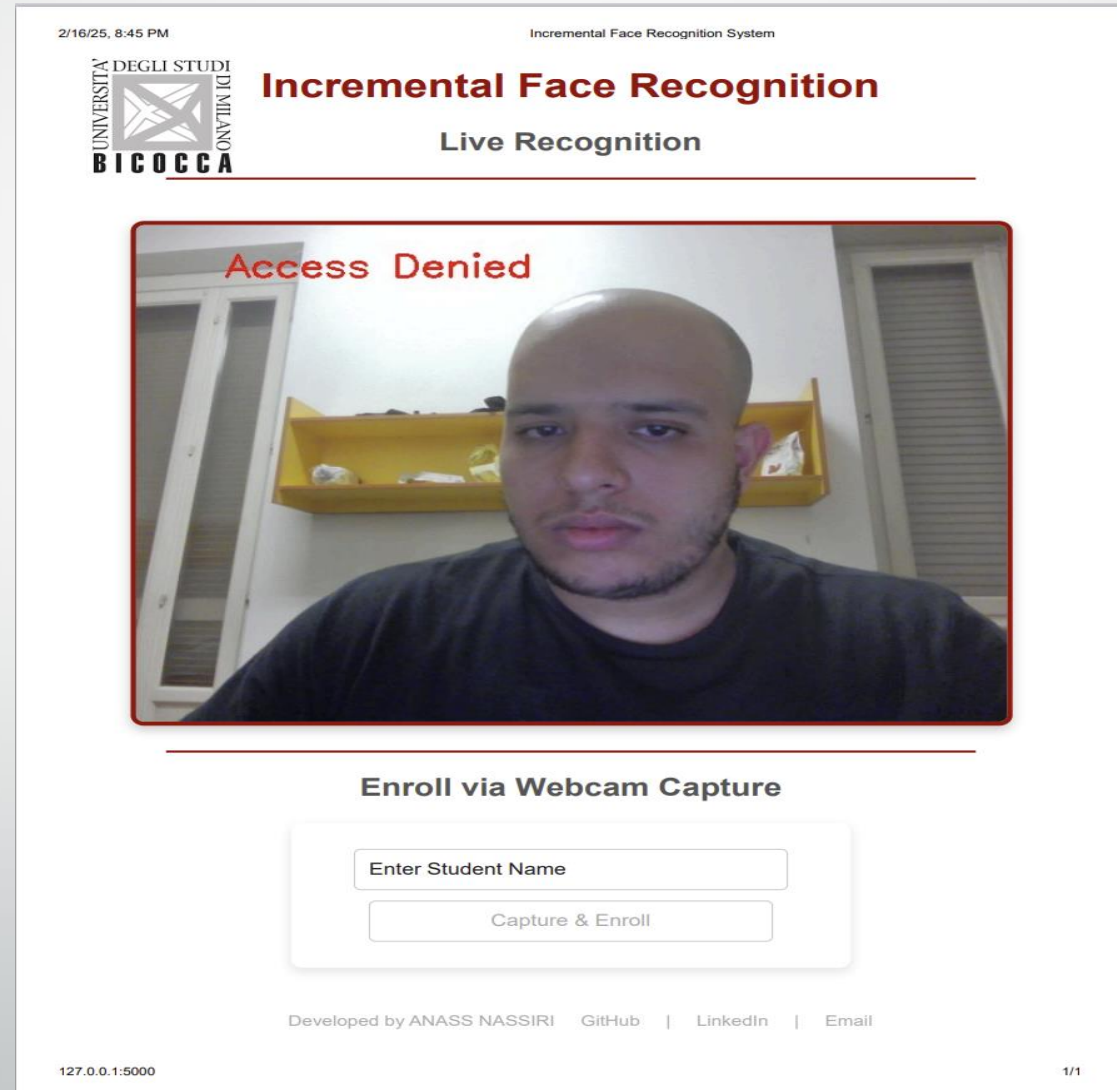

This figures before and after i add my self using the incrimental learnig system

# Results

Here the system doesn't recognize me, because i didn't train it on my face , I want to test the system by my face .

- I deploy it in web applicationig using FLASK framework

Here after I added my self by capturing my picture and entering my name, immediately the incremental algorithm works and starts recognizing my face

# Hardware and environment

The hardware I used for computation for the entire project is :

- i714700hq CPU
- GPU NVIDIA RTX 4070, Cuda API
- RAM 32 GB

For capturing the Images:

- Laptop webcam fullHD

The Environment used:

- VS CODE collab notebook style
- Pytorch,

# Practical testing

# Conclusion

- Incremental face recognition provides an efficient, real-time approach to student authorization
- The system enables dynamic learning without the need for full model retraining.
- Accurate and scalable, ensuring long-term usability in real-world applications.

## Future work

- Deploy the system on edge devices or embedded hardware (Jetson Nano, Raspberry Pi).
- Extend functionality to multi-camera networks and cloud-based authentication.
- Optimize storage and retrieval of face embeddings for large-scale deployments.
